

The 40 dB interval excludes zero and lies below the registered floor; the 20 dB interval does not overlap it

Markers are means; bars are 95% percentile bootstrap CIs over seeds. The registered H1 rule requires the 40 dB difference to exceed the floor AND Wilcoxon $p < 0.05$; it meets neither. Study 1's interval is wider because $n = 10$ and its endpoint is the lung channel at ceiling; it is shown for completeness, not as a comparable estimate.
