

The advantage becomes detectable between 40 and 35 dB and clears the registered effect-size floor between 35 and 30 dB, on the suppressed channel

(a) Paired across the 58 registered seeds; bands are 95% percentile bootstrap CIs. Difference-of-differences $D(20\text{ dB}) - D(60\text{ dB}) = +1.937$ points, CI [+1.400, +2.465], which is the registered H3 statistic.
(b) Each seed's gain divided by B_{wide}'s own remaining error at that level, so the two ceilings cancel. Not preregistered: descriptive, and the heart-versus-lung contrast cannot confirm or falsify the mechanism. Lung values at 60–40 dB divide by an error under 0.7 points and are not interpretable; their intervals all contain zero.
